21st Sept 2019

Array

C++ | Java

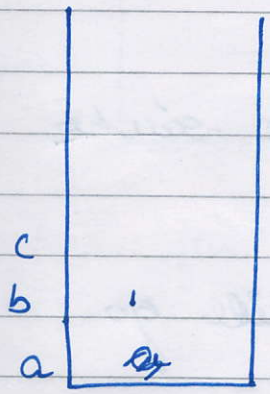
int arr[100]; | int [] arr = new int [n];

stack is being alotted by operating system.

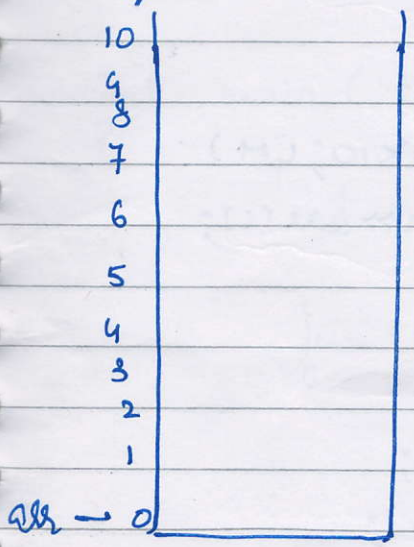
Memory allocation.

stack heap.

int a, b, c, ---



padding concept in stack where empty space is present between variable in stack

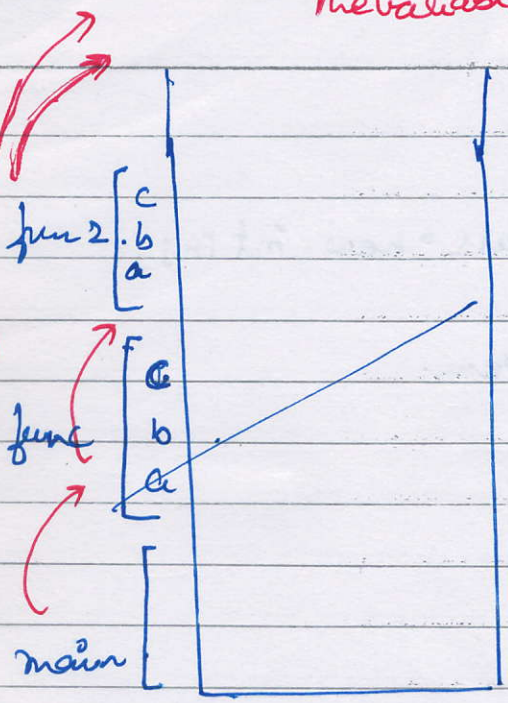


int = 4 byte.

while moving up variable is being created
when function is coming down all the variables will be dead with time.

fun1.cc fun2.cc.

Me variables different according to OS.



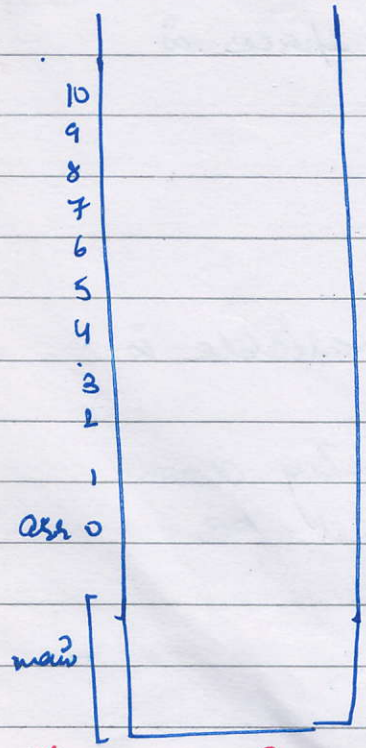
```
void fun2(a,b,c)
{
    cout<<a+b-c;
}

void fun()
{
    int a,b,c;
    fun2(a,b,c);
}

int main().
{
    fun();
}
```

→ once fun is completed the variables a,b,c will be wipped out.

→ once the function completes its task it will go back to its parent.



```
int[] fun(){
{
    int arr[10];
    for(int i=0; i<10; i++)
    {
        cin>>arr[i];
    }
}

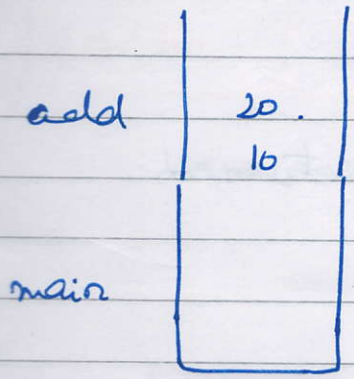
int main() {
    int arr[];
    arr = fun();
```

This code will work but when will try to access the element of arr it would be different because the arr is already

100 | 36 (136) 40

100
70
30
200 | 20

copy constructor → whenever a function returns something or argument is passed for function. copy constructor is invoked



→ when main is calling add() it is actually copying the values of variable. (by copy constructor)

int *fun(int n) → pointer to first index is being returned (i.e base address)
{
    int arr[n];

    return arr;
}

int main()
{
    int n=10;

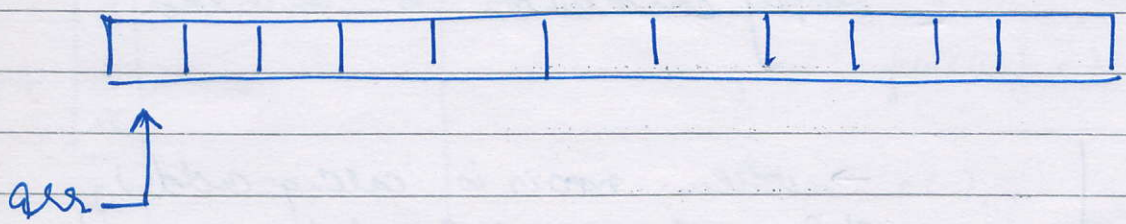
    fun(n);

}

byte: 4 8 1

int, long, char, string } primitive

* when you return it, it is being copied.



base

in Non-primitive ^ address is being returned.

```
void fun (int arr[])
{
    for(int i=0; i<20; i++)
    {
        cout<<arr[i]<<" ";
    }
}

int main()
{
    int n=10;
    int arr[n];
    fun(arr);
}
```

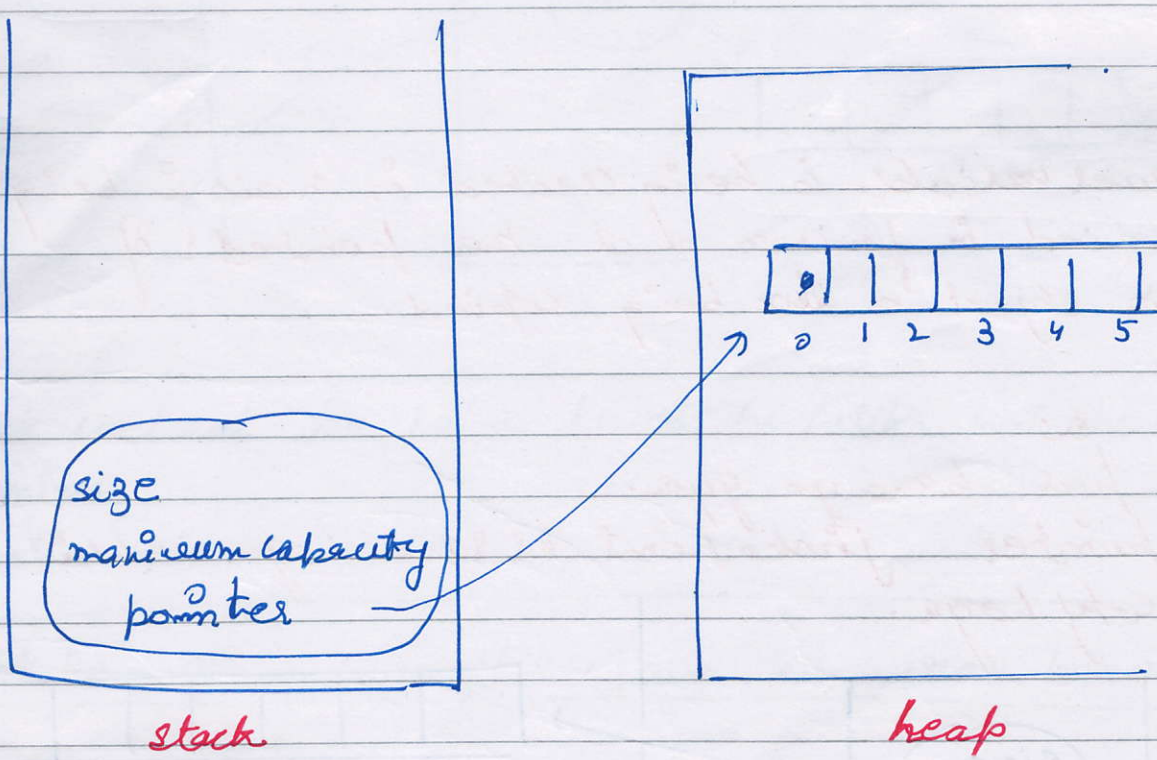
we passed an array of 10 size but the function only copies the base address so when we pass it create it still so it will work.

```
void fun( int arr[], int n)
{
for(int i=0; i<n; i++)
{
}
}
```

→ we should always send size of array because it helps in defining size.

Vector

```
vector<int> arr(n,0);
```



gcc 14 10 lakh. capacity of vector.

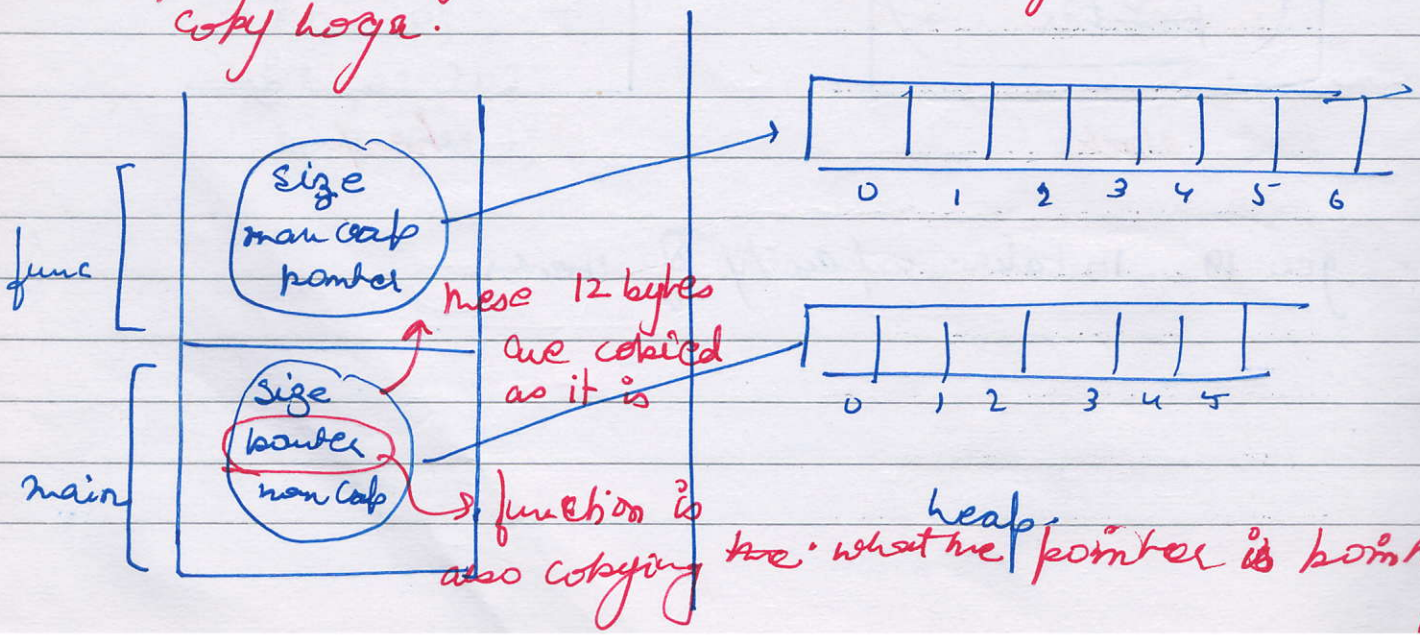
```
void fun(vector<int> arr)
{
    for(int i=0; i<arr.size(); i++)
        cout<<arr[i]<<;
}

}

int main()
{
    vector<int> arr(n,0);
    fun(arr);
}.
```

whatever variable is being created in main is being copied in function and the pointer of main object is also being copied.

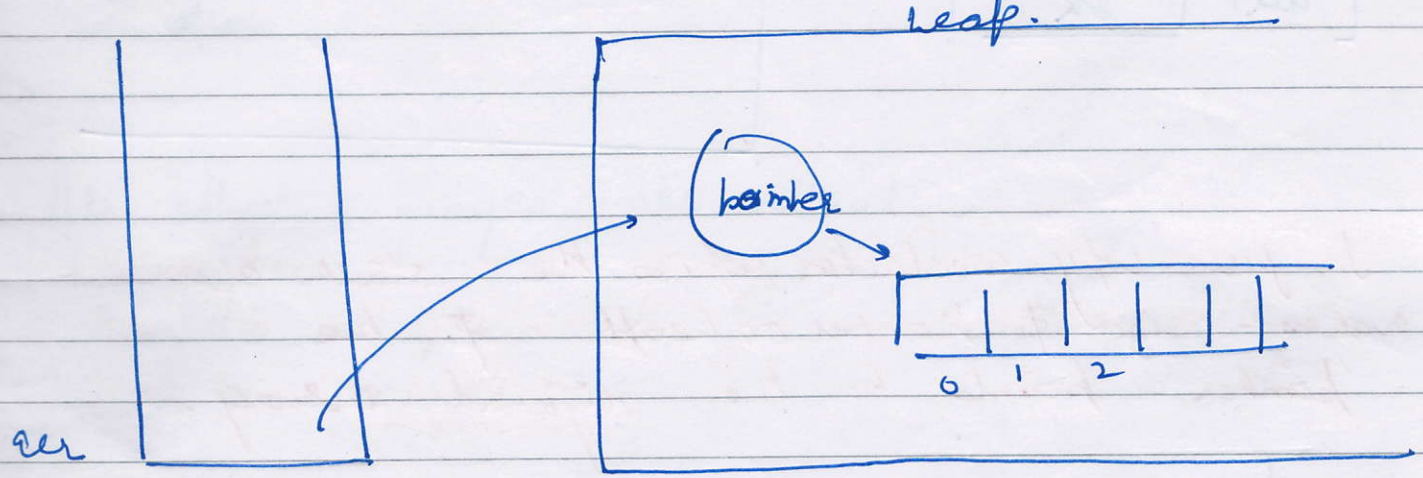
∴ a
stack par banaya gaya.
↳ pointer jiske paas hoga wo bhi copy hoga.



→ behind the scene there is a loop to copy vector which of O(n)
→ It is being envoked twice while going up while going down.

Java

pointer ko heap pe banana do.



stack pe heap pe jane ka ek hi tarika hai hoise pointer

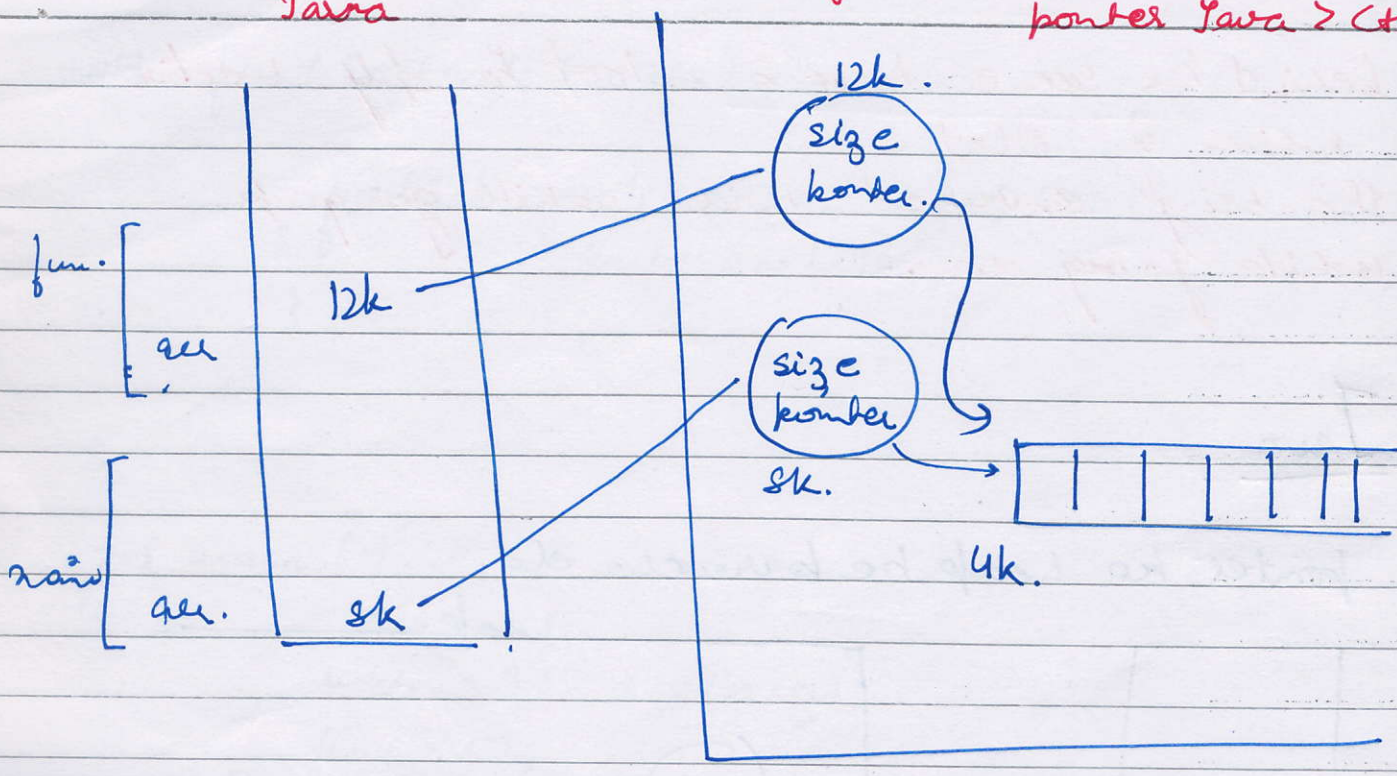
project:

C++ ka array use krke java ka array banana

[new keyword → creation on heap.]

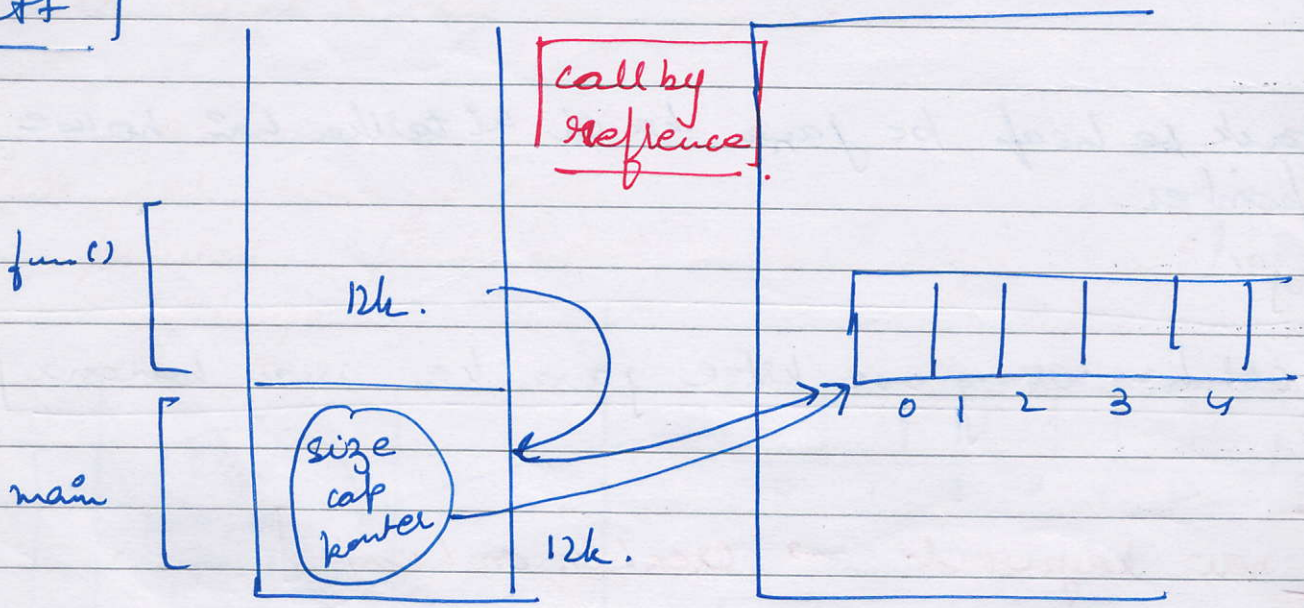
No. of pointers to access array element is greater in java than C++.

pointer Java > C++.

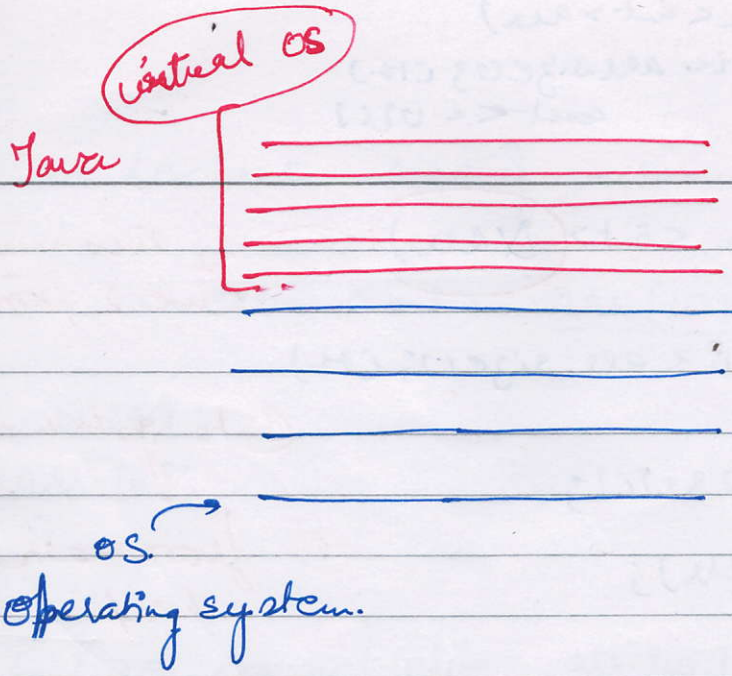


In java copy constructor copies the stack element makes a size & pointer on heap & the pointer points to the original array.

C++



The function copies the address of main and which is further pointing to our heap.



OS → Operating system.

as C is nearest to OS hence it will execute fast than others.

All other languages make virtual OS.
Since there are a No. of layers of abstraction hence it is not preferred for competitive coding.
same is with python.

In C++ vector is having fast implementation because it uses less pointers than that being used in other language.

* Accessing elements on stack is easiest job i.e if we make array on stack.

```
void display (vector<int> arr)
{
    for(int i=0; i<arr.size(); i++)
        cout << v[i]
}
```

```
void input (vector<int> &arr)
{
    for(int i=0; i<arr.size(); i++)
    {
        cin >> arr[i];
    }
    display(arr);
}

int main()
{
    vector<int> arr(n);
```

this will have 2 pointers

① to go to main

② from main to heap.

```
void display (vector<int> & arr)
{
    for (int i : arr)
    {
        cout << i << " ";
    }
}
```

(for each) value loop

index be lekin loop be kaam leta hai

to get values of array

vector is dynamic → grows in size.

push_back()	O(1)

(n)

Once we reach capacity we take O(n) operation to copy n size vector & O(1) to push_back

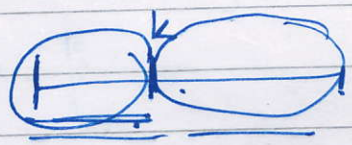
If we declare size of vector.

vector <int> arr(10,0);

arr[9];
arr[6];

but we cannot write arr[10]
because its size is fixed.

So if we use push_back it will grow the size of vector by 2. and push back.



(0, n-k-1).

(n-k, n-1)

(0, n-1)

(i) max
min.

(ii) find (int [] arr, int data)

reverse (int [] arr, int si, int ei).

↳ $\frac{(k-1-0+1)+(l-1-k+1)+(l-1-0+1)}{2}$.

$\frac{2l}{2} \rightarrow l$.

O(n)

reverse (0, n-k-1);
reverse (n-k, n-1);
reverse (0, n-1);

22nd Sept 2024.

Binary Search.

→ whenever we have monotonically increasing or decreasing data.

Lower bound.

```
while (si <= ei)
{
    int mid = (si+ei)/2;
    if (arr[mid] == data)
    {
        if (mid-1 >= 0 && arr[mid-1] == arr[mid])
        {

·k=1

bit ON. 111 7

210

No

101 5

210

if k=2.

off 001 1

No. of set bits

1 1 0 1 1 0 1 1 1 → No. of setbits = 7

7 →	111	→ 3
5 →	101	2
4 →	100	1
10 →	1010	2.

```
int num = n;
for(int i=0; i<32; i++)
{
    int mask = 1<<i;
    if((mask & num) != 0)
    {
        count++;
    }
}
```

as this loop is being executed 32 times

```
1
10
100
1000
10000
```

This will run infinite time.

optimized

```
while(num!=0)
{
    if((num&1)!=0)      // check last bit
    {
        count++;
    }
    num = num>>1;       // right shift discard LSB.
}
```

if we have

1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 .

above code will not work because always 1 will be append from MSB.

```
int l=0;
while ( num!=0 && l<32 )
{
    if(( num & 1 )!=0 )
    {
        count++;
    }
    max >>= 1;
    l++;
}
```

Java will be preferable for right shift because it will always append '0'.

1. If a No. is power of 2 or Not

No. ① Take 1st complement.
② XOR complement & original No

```
int temp=num;
num ^= (~num);
if ( num==-1)
{
}
```

Inf

return ((n & (n-1)) == 0) ? true : false ;

for 8. 1000.

take 7. 111

(& 0000)

if NO. becomes 0 it is of form 2^n. i.e can be expressed in power of 2.

table in database.

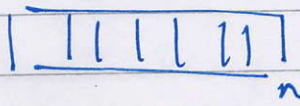
import java.util.ArrayList;

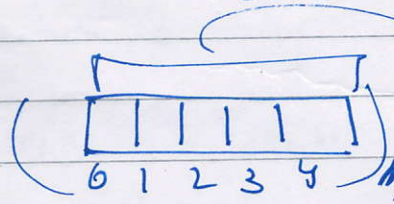
java. Integer	C++.
ArrayList<Integer> arr = new ArrayList<>();	vector
grow with 1.5 x speed.	grow with 2X speed.
get arr.get(idx);	arr(idx)
without size arr.add(val);	arr.push_back(val);
with size. arr.set(idx, val);	arr[idx] = val.
we prefer without size.	
remove. arr.remove(idx); O(n) function.	arr.erase(arr.front()+idx



if we ask to remove first element it is condition dependent because entire array will be copied

Each Remove → O(1)

size .size() .size()



to access in given size use [] → vector .set in AL.

to access virtual memory we have to use push_back & .get.

abc → -, a, b, c, ab, bc, abc

return type : Java

```
public static ArrayList<String> subsequence (String str);
{
    if (str.length() == 0)
    {
        ArrayList<String> base = new ArrayList<>();
        base.add("");
        return base;
    }
    char ch = str.charAt(0);
    String ros = str.substring(1);

    ArrayList<String> recAns = subseq(ros);

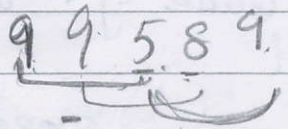
if you burst balloon.



arr[3]

cost = arr[2] * arr[3] * arr[4].

i-1 i i+1

if i==0 || i==length

arr[i-1] = 1 length += 1

Order in which balloon is burst.

17th/NOV/2014.

Merge two array.

arr1 | 2 | 8 | 12 | 14 | 18 | 36 |

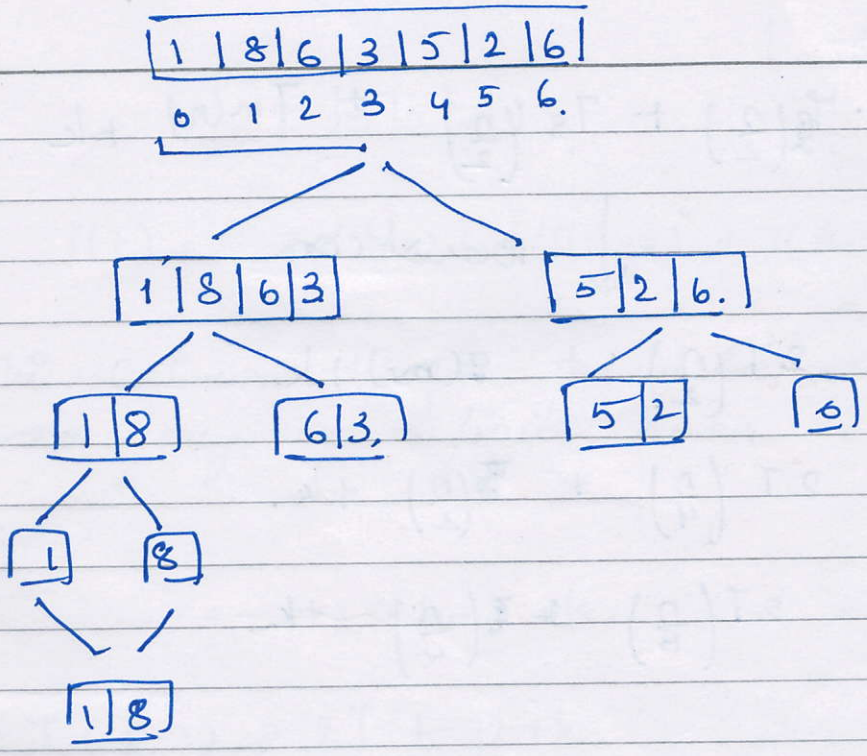
arr2 | 4 | 6 | 12 | 17 | 29 | 54 | 94 |

```
int[] merge = new int [ arr1.length + arr2.length].
  while( i< arr1.length. && j < arr2.length)
{
        if ( arr1 [ i] < arr1[j].
       {
              merge [k++] = arr1[i++] ;
       }
       else.
              merge [k++] = arr2[j++];
       }
}
  while ( i< arr1.length)
  {       merge [k++]= arr1 [i++];
  }
  while (j < arr2.length)
  {
        merge [k++]= arr2 [j++];
  }
```

1/ one single array is given and we assume it to be containing two array

| 1 | 3 | 7 | 9 | 15 | 2 | 4 | 6 | 11 | 13 | 14 |

for this we will be needing indexes.



```
if (li => ri)
{
    int[] base = new int[1];
    base[0] = arr[li];
    return base;
}
int mid = (li+ri) >>>1;
```

Time complexity.

```
int[] left = merge (arr, lo, mid);
int[] right =      (_, mid+1, hi);

int[] merge = mergeSort(left, right);
return merge;
```

time complexity depends on those 3 calls.

T(n) =

$$T(n) = T_1\left(\frac{n}{2}\right) + T_2\left(\frac{n}{2}\right) + T_m(n) + k.$$

↓ worst com

$$T(n) = 2T\left(\frac{n}{2}\right) + g(n) + k.$$

$$2T\left(\frac{n}{2}\right) = 2^2T\left(\frac{n}{4}\right) + 2g\left(\frac{n}{2}\right) + 2k.$$

$$2^2T\left(\frac{n}{4}\right) = 2^3T\left(\frac{n}{8}\right) + 2^2g\left(\frac{n}{4}\right) + 2^2k.$$

⋮

we are multiplying so that we can cut out the common terms.

$$T(n) = 2^kT\left(\frac{n}{2^k}\right) + (n+p)k.$$

t target

coin 2 | 3 | 5 | 7.

$T(t) = T(t-2) + T(t-3) + T(t-5) + T(t-7) + k.$

[If minimum height would be when we will choose only 2 infinite times

worst case:

$= 2T(t-2) + k.$

$T(t-2) = 2T(t-4) + k.$

$T(t-4) = 2T(t-6) + k.$

!

$T(t) = 1^{\left(\frac{t}{2}\right)} + (1 + 1^2 + \dots)k.$

height of 1 is target smallest no.

sudoku.

$T(n) = \sum_{i=1}^{9} n_i + n^2$

$= n^2 \sum_{i=1}^{9} n_i$

Q1

q^{n^2}

$T(n) =$ $\cdot T$.

$q\,T(n) \simeq q^2 T(n-1) + \dots$

$q^{n^2} + q^{n^2} \cdot n^2$.

Sudoku. $(q^{n^2})(n^2)$ [7]

with bit q^{n^2}

q

$(1 \dots q)^{n \times n}$

Coin — subsequence

1. permutation
   combination -

2. single coin

Subsequence

1. Combination.

target is having indices.

(0,8) (1,10) (0,10)

target is accepting coin or not

Combination - Repetition

```
(1)
if( tar >=0 || idx == all.length ).
{       if(tar >=0)
        {
        }
}
```

Combination - No Repetition

(2) combination without repetition here as (idx+1).

```
if(tar - arr[idx] >=0)
{       comb( arr, idx, tar - arr[idx], ans + str[idx]);
}
        comb( arr, idx+1, tar, ans );
```

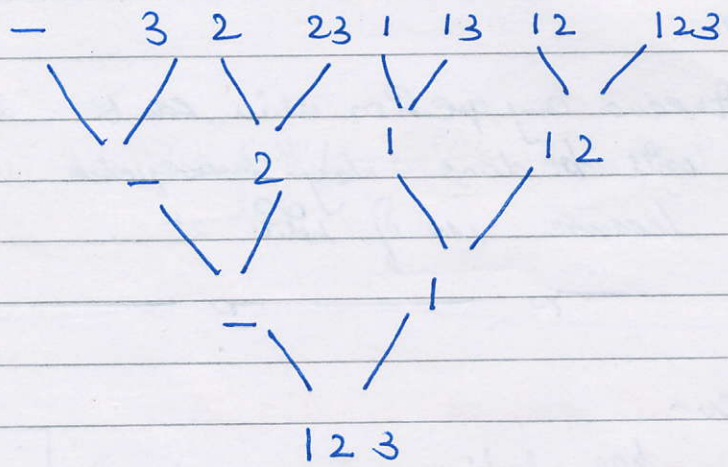
(3) permutation put "0" for permutation without repetition.

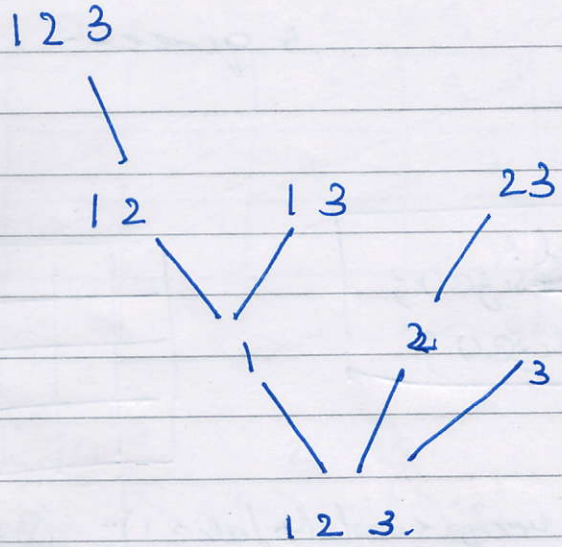
Permutation
Repetition.

(4) Permutation - No Repetition - use visited.

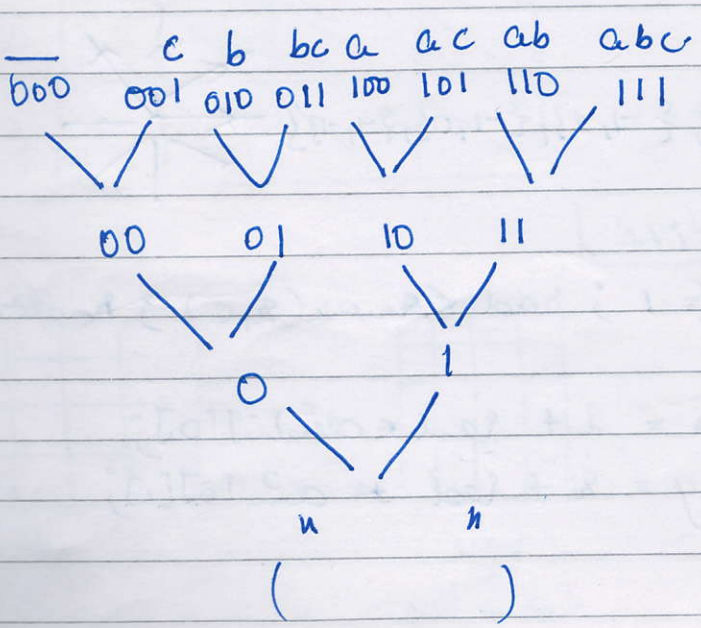
String.

[ ],
[1],
[1, 2],
[1, 2, 3],
[1, 3],
[2],
[2, 3],
[3],





Combination.
pre order
print.



Bit Tree
Same as
subsequence tree

kya the hai yani kata ke ? ?

$(x+1)^n =$

put $x=1$

2^n

It means any question which can be done by combination will be done by subsequence also & by bit because no. of bit is 2^n.

Queen

permutation

comb

3 queen

6/Jan/2020.

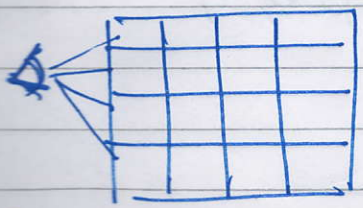
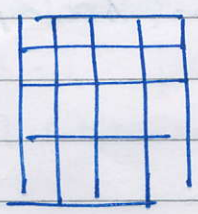
add size of col-1

[x - y + col. length - 1 .

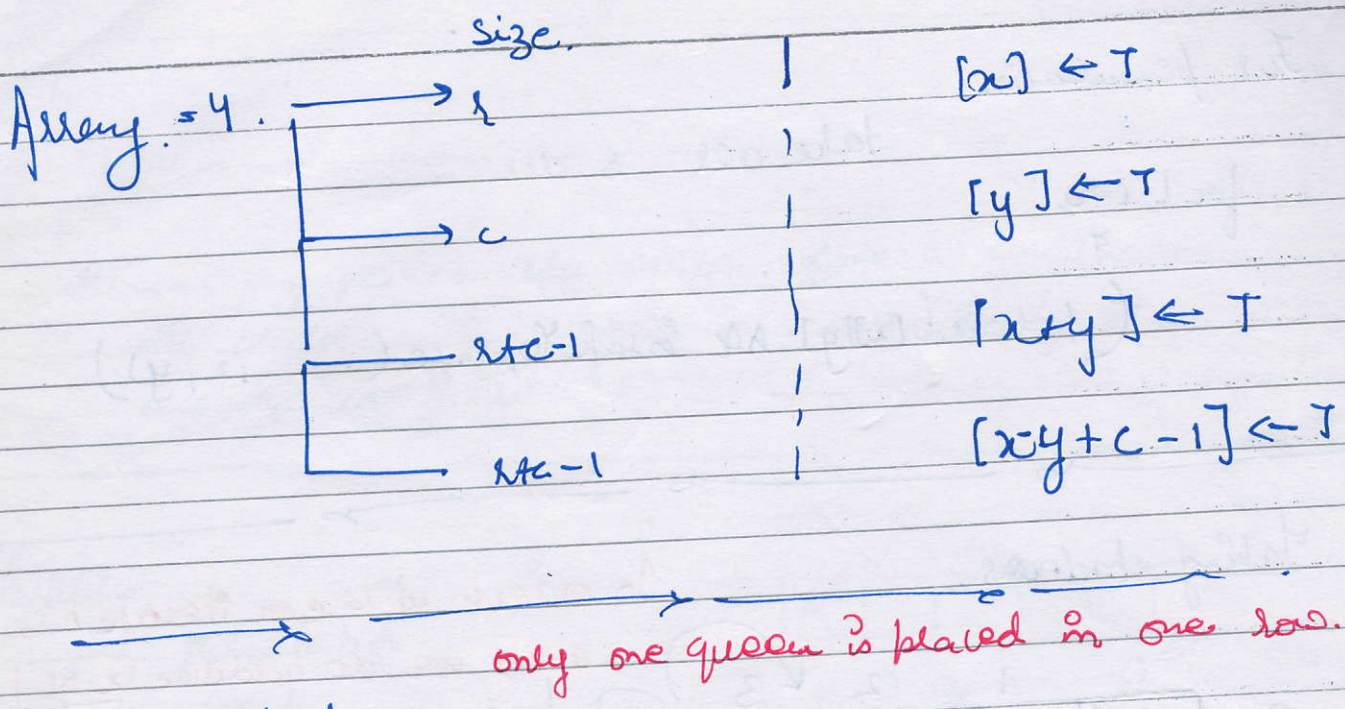
to mark whether
queen is present or



row mask.



col mask.

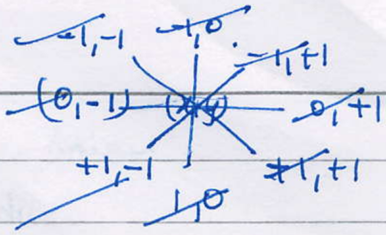


Another method.

Instead of sending next position for placement of queen. in each row. we are supposed to place one queen.

```
int queen(vector<vector<bool>> &board, int
    if( row == board.size || q == 0)
    {
        if(q == 0){
        }
    }
for(int col = 0; col < board[0].size(); col++)
    if( !board[x][y], && isSafe(board, row, col)
    {
        board[row][col] = true;
        count += queen(board, row+1, q-1,
```

11th Jan 2020



```
# define vi vector <int> vi;
# define vvi vector <vi> vvi;
# vb vector <bool> vb;
# vvb vector <vb> vvb;
```

not required

```
int queen ( int row, int tnq, vvb &board, vb &col,
                       vb &diag, vb &adiag, string ans)
int n = col.size();
  if( row == n || tnq == 0)
  {      if ( tnq == 0).
      {     cout <<ans
            return 1;
      }
      return 0;
  }
```

instead of this we pass n over here

we can do this on col.size.

```
int count = 0
for (int c = 0; c < n; c++)
     if( !col[c] && !diag[r+c] && !adiag[r-c+n-1]
     {
          col[C] = true;
          diag[r+c] = true;
          adiag[r-c+n-1] = true;

        count += queen(row+1, tnq-1, board, col, diag, adiag, ans + row + col.)
          col[c] = false;
          diag[r+c] = false;
          adiag[r-c+n-1] = false;
     }
}
return count;
```

main.

```
vb col (1, false)
vb diag (2*n, false)
vb adiag (2*n-1, false);
int n;
int queen(int r, int mq, int &col, int &d
```

```
int count = 0;
for(int c=0; c<n; c++)
    int w = 1<<c;
    x = 1<<(r+c);
    y = 1<< (r-c+n-1);

if(!(col&w) && !(diag&x) && !(adiag&y))
{
    col |= w;
    diag |= x;
    adiag |= y;

    count += queen(r+1, mq, col, diag, adiag,
                   ans+(r*n+c));

    col |= w;
    diag |= x;
    adiag |= y;
}

}
```

int col = 0;
int diag = 0
adiag = 0;

} for bits operations

Sudoku.

instead of making width call we call above one

```

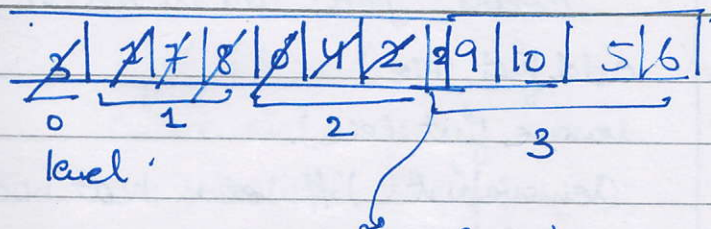
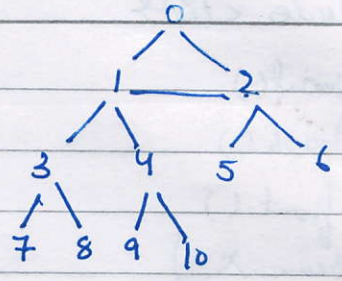
BFS.

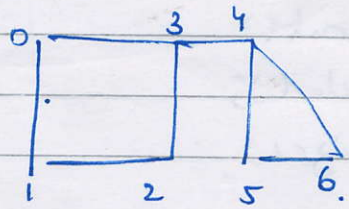
14 July Sunday 20

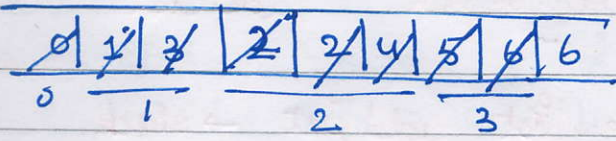
BFS is a good algo to find cycle wrt to a given source.



as 2 is coming twice it is implying that there is cycle.







∴ No. of edges to reach 6 from 0 is 3.

If any no which is already visited is encountered in graph we will say here is a cycle.

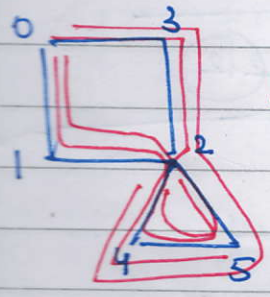
0 source ke respect mein we are always pushing unvisited element in queue. we are getting 2 cycle.

Shortest path in terms of length.

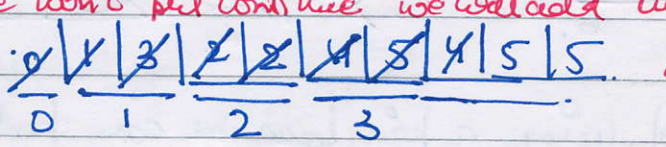
add continue in order to avoid this

```
for cycle & destination.
if (vis[ele]) cycle++;
                continue;
```

1. queue of int, vis
2. queue ← src.
3. while (queue.size() > 0)
   - 3.1 remove first of queue.
   - 3.2. vis ← ele.
   - 3.3 For all unvisited nbr's
     - 3.3.1 que ← nbr's



If we won't put continue we will add unvisited neighbours which will increment cycle count.



① ② ③ ④

If we won't put continue in bfs it will give all different paths to traverse in cycle.

Here here are 4 ways | 0 ke respect mein sabhi edges ko traverse kiya he aaya.

queue <int> que = new LinkedList <>(); Java.

C++

```
#include <list>
push_front()
push_back()
pop_front()
(return x)
front()
back();
size()
```

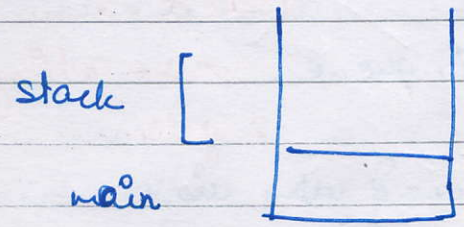
Java

```
import java.util.LinkedList;
addFirst(ele)
removeFirst(ele).
removeFirst(); // return that node.
getFirst()
getLast()
.size()
```

removeFirst addLast to make queue.

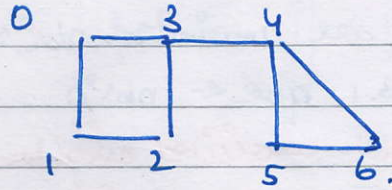
removeFirst addFirst → stack.

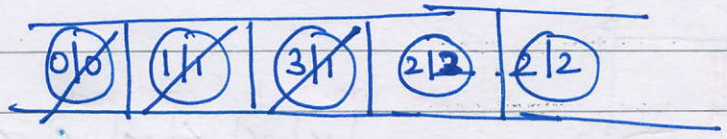
* Array de stack banta hai queue nhi banta.



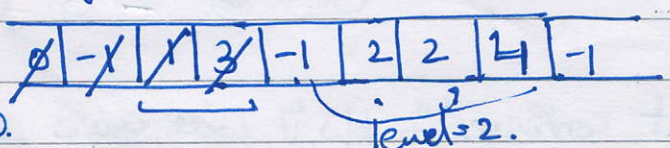
Importing library file in program leads to firing of copy constructor. which is costly.

Heap tak pahunchne mein aur stack tak pahunchne mein stack is more efficient. ∴ if we make array on stack - it is efficient.





Instead of using a pair class we can put null



```
void bfs( int src)
{       queue<int> que;
        vector<int> vis(n, false);

        que.push( src);
        que.push(-1);
        int cycle = 0;

        while( que.size() != 1).
{       int curr = que.front();
            que.pop();
        if( curr == dest){ cout<<level. }.
        if( vis[curr]) { cout << "cycle" << cycle++ <<endl;
                         continue; }.

        vis[curr] = true;
        for( Edge* e : graph[curr])
{           if( ! vis[e->v])
            {   que.push(e->v);
            }
        }

    if( que.front() == -1)
    {       level++;
            que.pop();
            que.push(-1);

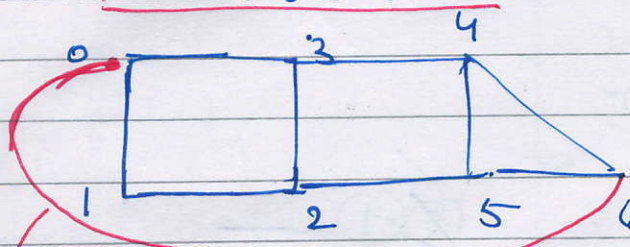
    }

}
```

18th January

Total no. of vtx − 1 — If we need minimum no. of edges to connect graph without creating cycle.

Hamiltonian Path

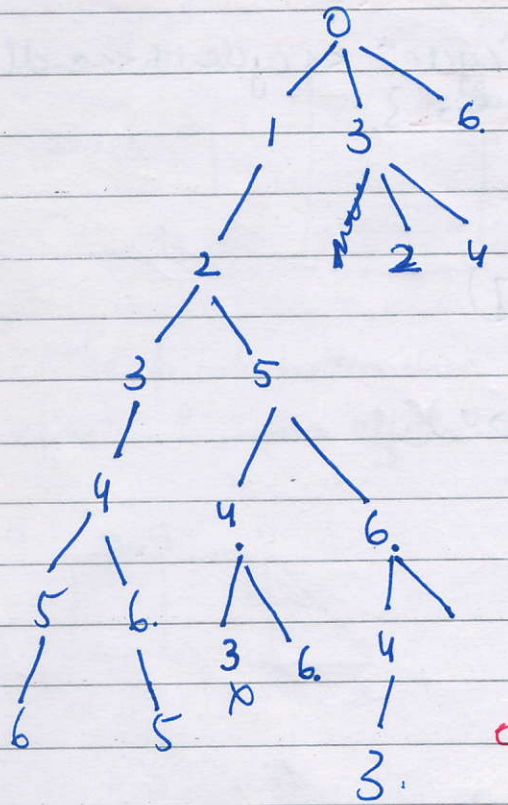


visiting each vertices exactly once.

0 1 2 3 4 5 6
0 1 2 3 4 6 5
2 1 0 3 4 5 6
2 1 0 3 4 6 5

Hamiltonian path & Hamiltonian cycle.

If there is a direct edge between source & destination after all edges are traversed is called hamiltonian cycle.



base case when total no. of count = one less than size(v) − 1.

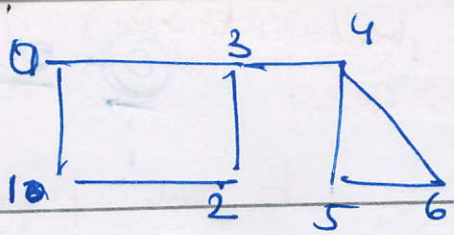
```
int hamiltonianpath( int vtx, vector<bool>&vis)
                     int vtxcount, int osource
{ (1) if( vtxcount == graph.size()-1)
  { (2) for( Edge e: graph[vtx])
        { (3) if( e->v == osource)
              cycle.
          int count = 0;
          vis[vtx] = true;
          for( Edge *e : graph[vtx]) flag = true;
          { if(!vis[e->v])
            {
              count += hamiltonianpath(e->v, vis,
                       ans + to_string(vtx)
                       vtxcount+1);
                       osource.
            }
          }
  }
  vis[vtx] = false;
}
```

(2.2)

```
if(!flag)
{
  cout << ans + to_string(vtx) << endl;
}
return 1;
}
```

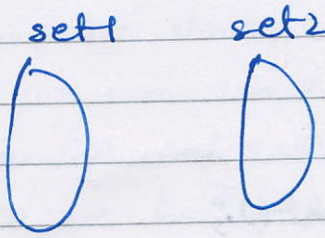
path: 0 1 2 3 4 6 5

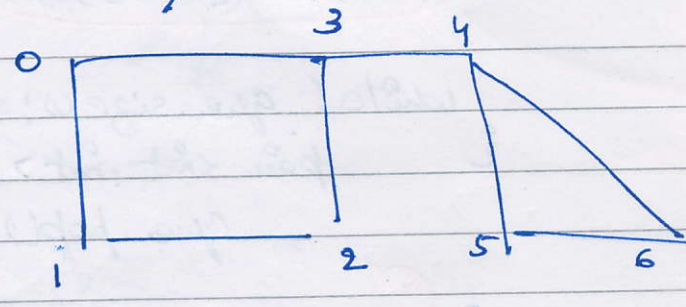
cycle:
0 1 2 3 4 5 6
0 1 2 5 6 4 3
0 3 4 6 5 2 1
0 6 5 4 3 2 1

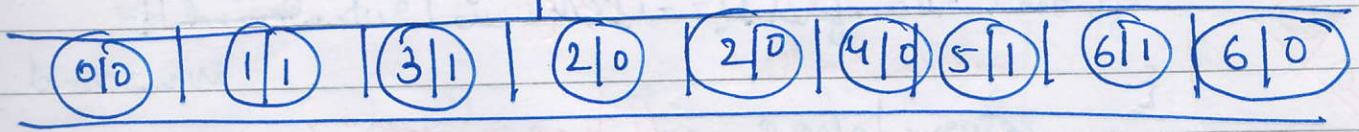


Bipartite.

Graph is to be divided in two sets such that No two adjacent vertex are in same set.







queue.

add 0 with 0.

unvisited neighbour $(0+1)\%2$

val associated with node update in vis array.

```
0 → -1
1 → -1
2 → -1
3 → -1
4 → -1
5 → -1
6 → -1
```

1. vis<int>. default -1
2. que ← (src|0)
3. while(!que.size())
   - 3.1 remove vtx
   - 3.2 check for contradiction.
   - 3.3 marks remove vtx to vis
   - 3.4 for all unvisited vtx
   - 3.4.1 que ← nbr.

* graph may be of type

for this que is to be done first

```
bool isBipartite(){

    vector<int> vis(graph.size()-1);
    queue<pair<int,int>> que;

    for(int i=0; i<graph.size(); i++)
    {
        if(!vis[i])
        {
```

```
bool bipartitehelper( int i ,vector<int> &vis)
    que<pair<int,int>> que;
    bool flag = true;
    que.push({i,0});

    while( que.size()!=0)
    {   pair<int,int> curr = que.front();
        que.pop();

        if( vis[ curr.first]!= -1)
        {   cout << "conflict"
            return false;
            continue;
        }
        vis[ curr.first] = curr.second;

        for( edge* e : graph[curr.first])
        {   if( !vis[e->v])
            {   que.push( {e->v , (curr.second+1)%2} );
            }
        }
        //cout << count << " " << (boolalpha)<< flag <<endl;
    }
    return flag;
}
void bipartite ()
    vector<int> vis (graph.size()-1) ;

{   for(int i=0; i< graph.size(); i++ )
    {   if( vis[i] == -1)
        {   cout << count << (boolalpha)<< bipartitehelper(
            count++;
        }
```

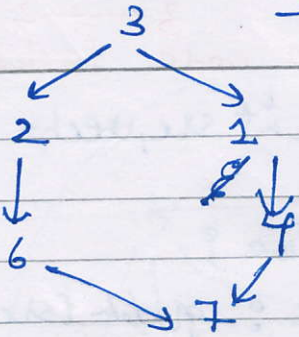
Directional Graph.

Leetcode

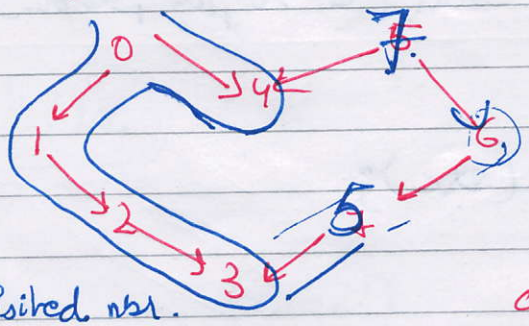
Course schedule

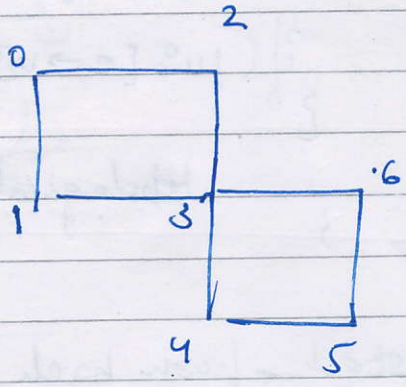
Course schedule II

If we want to study courses but we can read it when the dependent courses are being read.



here we will make stack using array





DFS

1. vis
2. for del unvisited nbr.
   add nbr

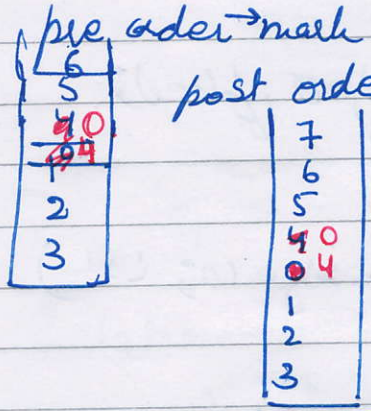
u → v jaana chahte ho ie we should always get forward edge.

0 –
1 –
2 –
3 –
4 –
5 –
6 –
7 –

pre order → mark time

post order → add in stack

put in stack

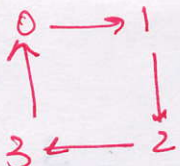


Reverse order of stack

Ans 7 6 5 0 4 1 2 3.

1. mark, src.
2. for all unvisited nbr
   DFS (nbr);
3. ans.stack.push(src)

(src, vis, ansstack)



This code lacks ability to detect cycle.

```
void topologicalSort(int src, vector<bool>& vis, vector<int>& stack)
{
    vis[src] = true;
    for(Edge *e : graph[src])
    {
        if(!vis[e->v])
        {
            topological_sort(e->v, vis, stack);
        }
    }
    stack.push_back(src);
}

void topological()
{
    vector<bool> vis(graph.size(), false);
    vector<int> stack;

    for(int i=0; i<graph.size(); i++)
    {
        if(!vis[i])
        {
            topological sort(i, vis, stack);
        }
    }

    while(!st.isEmpty())

    while(st.size() != 0)
    {
        cout << stack.back() <<
        stack.pop_back();
    }
}
```

.bool()
.beach()
